The built-in functions	331	38
Cleaning up	455	42
System-dependent changes	467	43
Index	479	46

1* **Introduction.** BIBTEX is a preprocessor (with elements of postprocessing as explained below) for the L^AT_EX document-preparation system. It handles most of the formatting decisions required to produce a reference list, outputting a `.bbl` file that a user can edit to add any finishing touches BIBTEX isn't designed to handle (in practice, such editing almost never is needed); with this file L^AT_EX actually produces the reference list.

Here's how BIBTEX works. It takes as input (a) an `.aux` file produced by L^AT_EX on an earlier run; (b) a `.bst` file (the style file), which specifies the general reference-list style and specifies how to format individual entries, and which is written by a style designer (called a wizard throughout this program) in a special-purpose language described in the BIBTEX documentation—see the file `btxdoc.tex`; and (c) `.bib` file(s) constituting a database of all reference-list entries the user might ever hope to use. BIBTEX chooses from the `.bib` file(s) only those entries specified by the `.aux` file (that is, those given by L^AT_EX's `\cite` or `\nocite` commands), and creates as output a `.bbl` file containing these entries together with the formatting commands specified by the `.bst` file (BIBTEX also creates a `.blg` log file, which includes any error or warning messages, but this file isn't used by any program). L^AT_EX will use the `.bbl` file, perhaps edited by the user, to produce the reference list.

Many modules of BIBTEX were taken from Knuth's T_EX and T_EXware, with his permission. All known system-dependent modules are marked in the index entry “system dependencies”; Dave Fuchs helped exorcise unwanted ones. In addition, a few modules that can be changed to make BIBTEX smaller are marked in the index entry “space savings”.

Megathanks to Howard Trickey, for whose suggestions future users and style writers would be eternally grateful, if only they knew.

The *banner* string defined here should be changed whenever BIBTEX gets modified.

```
define my_name ≡ `bibtex`
define banner ≡ `This is BibTeX, Version 0.99d` { printed when the program starts }
```

2* Terminal output goes to the file *term_out*, while terminal input comes from *term_in*. On our system, these (system-dependent) files are already opened at the beginning of the program, and have the same real name.

```
define term_out ≡ standard_output
define term_in ≡ standard_input
```

⟨Globals in the outer block 2*⟩ ≡
`standard_input, standard_output: text;`

See also sections 16*, 19, 24, 30, 34, 37*, 41*, 43, 48*, 65*, 74, 76, 78, 80, 89, 91, 97*, 104, 117*, 124, 129*, 147, 161*, 163, 195, 219*, 247, 290*, 331, 337*, 344*, 365, 469*, and 472*.

This code is used in section 10*.

3* This program uses the term *print* instead of *write* when writing on both the *log_file* and (system-dependent) *term_out* file, and it uses *trace_pr* when in **trace** mode, for which it writes on just the *log_file*. If you want to change where either set of macros writes to, you should also change the other macros in this program for that set; each such macro begins with *print_* or *trace_pr_*.

```

define print(#) ≡
    begin write(log_file, #); write(term_out, #);
    end
define print_ln(#) ≡
    begin write_ln(log_file, #); write_ln(term_out, #);
    end
define print_newline ≡ print_a_newline { making this a procedure saves a little space }
define trace_pr(#) ≡
    begin write(log_file, #);
    end
define trace_pr_ln(#) ≡
    begin write_ln(log_file, #);
    end
define trace_pr_newline ≡
    begin write_ln(log_file);
    end
define log_pr(#) ≡ trace_pr(#)
define log_pr_ln(#) ≡ trace_pr_ln(#)
define log_pr_newline ≡ trace_pr_newline

```

(Procedures and functions for all file I/O, error messages, and such **3***) ≡

```

procedure print_a_newline;
    begin write_ln(log_file); write_ln(term_out);
    end;

```

See also sections 18, 38*, 44, 45, 46*, 47*, 51, 53*, 59*, 82, 95, 96, 98, 99, 108*, 111, 112, 113, 114, 115, 121*, 128*, 137, 138*, 144, 148, 149, 150, 153, 157, 158, 159, 165, 166, 167, 168, 169, 188*, 220, 221, 222, 226*, 229, 230, 231, 232, 233, 234, 235, 240, 271, 280, 281, 284, 293, 294, 295, 310, 311, 313, 321, 356, 368, 373, and 456.

This code is used in section 12.

4* Some of the code below is intended to be used only when diagnosing the strange behavior that sometimes occurs when BIBTEX is being installed or when system wizards are fooling around with BIBTEX without quite knowing what they are doing. Such code will not normally be compiled; it is delimited by the codewords ‘**debug** ... **gubed**’, with apologies to people who wish to preserve the purity of English. Similarly, there is some conditional code delimited by ‘**stat** ... **tats**’ that is intended only for use when statistics are to be kept about BIBTEX’s memory/cpu usage, and there is conditional code delimited by ‘**trace** ... **ecart**’ that is intended to be a trace facility for use mainly when debugging .bst files.

```

define debug ≡ ifdef(`TEXMF_DEBUG`)
define gubed ≡ endif(`TEXMF_DEBUG`)
format debug ≡ begin
format gubed ≡ end

define stat ≡ ifndef(`NO_BIBTEX_STAT`)
define tats ≡ endifn(`NO_BIBTEX_STAT`)
format stat ≡ begin
format tats ≡ end

define trace ≡ ifdef@&(`TRACE`)
define ecart ≡ endif@&(`TRACE`)
format trace ≡ begin
format ecart ≡ end

```

10* The main program. This program first reads the `.aux` file that L^AT_EX produces, (i) determining which `.bib` file(s) and `.bst` file to read and (ii) constructing a list of cite keys in order of occurrence. The `.aux` file may have other `.aux` files nested within. Second, it reads and executes the `.bst` file, (i) determining how and in which order to process the database entries in the `.bib` file(s) corresponding to those cite keys in the list (or in some cases, to all the entries in the `.bib` file(s)), (ii) determining what text to be output for each entry and determining any additional text to be output, and (iii) actually outputting this text to the `.bbl` file. In addition, the program sends error messages and other remarks to the `log_file` and terminal.

```

define close_up_shop = 9998 {jump here after fatal errors }
define exit_program = 9999 {jump here if we couldn't even get started }

  compute_hash_prime;

  initialize; {This initializes the jmp9998 buffer, which can be used early }
  hack0;
if verbose then
  begin print(banner); print_ln(version_string);

```

```

end
else begin log_pr(banner); log_pr_ln(version_string);
end;
log_pr_ln(`Capacity: max_strings=`, max_strings : 1, `, hash_size=`, hash_size : 1,
`, hash_prime=`, hash_prime : 1); (Read the .aux file 110*);
(Read and execute the .bst file 151*);
close_up_shop: (Clean up and leave 455);
if (history > 1) then uexit(history);
end.

```

13* This procedure gets things started properly.

(The procedure *initialize* 13*) ≡

```

procedure initialize;
var (Local variables for initialization 23*)
begin (Check the “constant” values for consistency 17*);
if (bad > 0) then
  begin write_ln(term_out, bad : 0, `is_a_bad`); uexit(1);
  end;
(Set initial values of key variables 20);
pre_def_certain_strings;
get_the_top_level_aux_file_name;
end;

```

This code is used in section 10*.

14* These parameters can be changed at compile time to extend or reduce BIBTEX’s capacity. They are set to accommodate about 750 cites when used with the standard styles, although *pool_size* is usually the first limitation to be a problem, often when there are 500 cites.

(Constants in the outer block 14*) ≡

```

hash_base = empty + 1; {lowest numbered hash-table location}
quote_next_fn = hash_base - 1; {special marker used in defining functions}
BUF_SIZE = 20000; {initial maximum number of characters in an input line (or string)}
min_print_line = 3; {minimum .bbl line length: must be ≥ 3}
MAX_PRINT_LINE = 60; {the maximum: must be > min_print_line and < buf_size}
aux_stack_size = 20; {maximum number of simultaneous open .aux files}
MAX_BIB_FILES = 20; {initial number of .bib files allowed}
POOL_SIZE = 65000; {initial number of characters in strings}
MAX_STRINGS = 4000; {minimum value for max_strings}
MAX_CITES = 750; {initial number of distinct cite keys; must be ≤ max_strings}
WIZ_FN_SPACE = 3000; {initial amount of wiz_defined-function space}
{min_crossrefs can be set at runtime now.}
SINGLE_FN_SPACE = 50; {initial amount for a single wiz_defined-function}
ENT_STR_SIZE = 100; {maximum size of a str_entry_var; must be ≤ buf_size}
GLOB_STR_SIZE = 1000; {maximum size of a str_global_var; must be ≤ buf_size}
MAX_GLOB_STRS = 10; {initial number of str_global_var names}
MAX_FIELDS = 5000; {initial number of fields (entries × fields, about 23 * max_cites for consistency)}
LIT_STK_SIZE = 50; {initial space for literal functions on the stack}

```

See also section 333.

This code is used in section 10*.

15* These parameters can also be changed at compile time, but they're needed to define some WEB numeric macros so they must be so defined themselves.

hash_size and *hash_prime* are now computed.

```
define HASH_SIZE = 5000 { minimum value for hash_size }
define file_name_size ≡ maxint { file names have no arbitrary maximum length }
      { For dynamic allocation. }
define x_entry_strs_tail(#) ≡ (#) ]
define x_entry_strs(#) ≡ entry_strs [ (#) * (ent_str_size + 1) + x_entry_strs_tail
define x_global_strs_tail(#) ≡ (#) ]
define x_global_strs(#) ≡ global_strs [ (#) * (glob_str_size + 1) + x_global_strs_tail
```

16* In case somebody has inadvertently made bad settings of the “constants,” BIBTEX checks them using a global variable called *bad*.

This is the first of many sections of BIBTEX where global variables are defined.

⟨ Globals in the outer block 2* ⟩ +≡

```
pool_size: integer;
max_print_line: integer;
max_bib_files: integer;
max_cites: integer;
wiz_fn_space: integer;
ent_str_size: integer;
glob_str_size: integer;
max_glob_strs: integer;
max_fields: integer;
lit_stk_size: integer;
max_strings: integer;
hash_size: integer;
hash_prime: integer;
hash_max: integer; { highest numbered hash-table location }
end_of_def: integer; { another special marker used in defining functions }
undefined: integer; { a special marker used for type_list }
bad: integer; { is some “constant” wrong? }
```

17* Each digit-value of *bad* has a specific meaning.

⟨ Check the “constant” values for consistency 17* ⟩ ≡

```
bad ← 0;
if (min_print_line < 3) then bad ← 1;
if (max_print_line ≤ min_print_line) then bad ← 10 * bad + 2;
if (max_print_line ≥ buf_size) then bad ← 10 * bad + 3;
if (hash_prime < 128) then bad ← 10 * bad + 4;
if (hash_prime > hash_size) then bad ← 10 * bad + 5;
if (hash_base ≠ 1) then bad ← 10 * bad + 6;
if (max_strings > hash_size) then bad ← 10 * bad + 7;
if (max_cites > max_strings) then bad ← 10 * bad + 8; { well, almost each }
```

See also section 302.

This code is used in section 13*.

22* Characters of text that have been converted to T_EX's internal form are said to be of type *ASCII_code*, which is a subrange of the integers.

```
⟨Types in the outer block 22*⟩ ≡
  ASCII_code = 0 .. 255; { eight-bit numbers }
```

See also sections 31, 36, 42*, 49*, 64*, 73*, 105, 118*, 130*, 160*, 291*, and 332.

This code is used in section 10*.

23* The original PASCAL compiler was designed in the late 60s, when six-bit character sets were common, so it did not make provision for lower-case letters. Nowadays, of course, we need to deal with both capital and small letters in a convenient way, especially in a program for typesetting; so the present specification of T_EX has been written under the assumption that the PASCAL compiler and run-time system permit the use of text files with more than 64 distinguishable characters. More precisely, we assume that the character set contains at least the letters and symbols associated with ASCII codes '40 through '176; all of these characters are now available on most computer terminals.

Since we are dealing with more characters than were present in the first PASCAL compilers, we have to decide what to call the associated data type. Some PASCALS use the original name *char* for the characters in text files, even though there now are more than 64 such characters, while other PASCALS consider *char* to be a 64-element subrange of a larger data type that has some other name.

In order to accommodate this difference, we shall use the name *text_char* to stand for the data type of the characters that are converted to and from *ASCII_code* when they are input and output. We shall also assume that *text_char* consists of the elements *chr*(*first_text_char*) through *chr*(*last_text_char*), inclusive. The following definitions should be adjusted if necessary.

```
define text_char ≡ ASCII_code { the data type of characters in text files }
define first_text_char = 0 { ordinal number of the smallest element of text_char }
define last_text_char = 255 { ordinal number of the largest element of text_char }
```

```
⟨Local variables for initialization 23*⟩ ≡
```

```
i: integer;
```

See also section 66.

This code is used in section 13*.

27* The ASCII code is “standard” only to a certain extent, since many computer installations have found it advantageous to have ready access to more than 94 printing characters. Appendix C of *The T_EXbook* gives a complete specification of the intended correspondence between characters and T_EX's internal representation.

If T_EX is being used on a garden-variety PASCAL for which only standard ASCII codes will appear in the input and output files, it doesn't really matter what codes are specified in *xchr*[1 .. '37], but the safest policy is to blank everything out by using the code shown below.

However, other settings of *xchr* will make T_EX more friendly on computers that have an extended character set, so that users can type things like '≠' instead of '\ne'. At MIT, for example, it would be more appropriate to substitute the code

```
for i ← 1 to '37 do xchr[i] ← chr(i);
```

T_EX's character set is essentially the same as MIT's, even with respect to characters less than '40. People with extended character sets can assign codes arbitrarily, giving an *xchr* equivalent to whatever characters the users of T_EX are allowed to have in their input files. It is best to make the codes correspond to the intended interpretations as shown in Appendix C whenever possible; but this is not necessary. For example, in countries with an alphabet of more than 26 letters, it is usually best to map the additional letters into codes less than '40.

```
⟨Set initial values of key variables 20⟩ +≡
  for i ← 0 to '37 do xchr[i] ← chr(i);
  for i ← '177 to '377 do xchr[i] ← chr(i);
```

28* This system-independent code makes the *xord* array contain a suitable inverse to the information in *xchr*. Note that if $xchr[i] = xchr[j]$ where $i < j < '177$, the value of $xord[xchr[i]]$ will turn out to be j or more; hence, standard ASCII code numbers will be used instead of codes below $'40$ in case there is a coincidence.

```
⟨ Set initial values of key variables 20 ⟩ +≡
  for i ← first_text_char to last_text_char do xord[xchr[i]] ← i;
```

32* Now we initialize the system-dependent *lex_class* array. The *tab* character may be system dependent. Note that the order of these assignments is important here.

```
⟨ Set initial values of key variables 20 ⟩ +≡
  for i ← 0 to '177 do lex_class[i] ← other_lex;
  for i ← '200 to '377 do lex_class[i] ← alpha;
  for i ← 0 to '37 do lex_class[i] ← illegal;
  lex_class[invalid_code] ← illegal; lex_class[tab] ← white_space; lex_class[13] ← white_space;
  lex_class[space] ← white_space; lex_class[tie] ← sep_char; lex_class[hyphen] ← sep_char;
  for i ← '60 to '71 do lex_class[i] ← numeric;
  for i ← '101 to '132 do lex_class[i] ← alpha;
  for i ← '141 to '172 do lex_class[i] ← alpha;
```

33* And now the *id_class* array.

```
⟨ Set initial values of key variables 20 ⟩ +≡
  for i ← 0 to '377 do id_class[i] ← legal_id_char;
  for i ← 0 to '37 do id_class[i] ← illegal_id_char;
  id_class[space] ← illegal_id_char; id_class[tab] ← illegal_id_char; id_class[double_quote] ← illegal_id_char;
  id_class[number_sign] ← illegal_id_char; id_class[comment] ← illegal_id_char;
  id_class[single_quote] ← illegal_id_char; id_class[left_paren] ← illegal_id_char;
  id_class[right_paren] ← illegal_id_char; id_class[comma] ← illegal_id_char;
  id_class[equals_sign] ← illegal_id_char; id_class[left_brace] ← illegal_id_char;
  id_class[right_brace] ← illegal_id_char;
```

37* Most of what we need to do with respect to input and output can be handled by the I/O facilities that are standard in PASCAL, i.e., the routines called *get*, *put*, *eof*, and so on. But standard PASCAL does not allow file variables to be associated with file names that are determined at run time, so it cannot be used to implement BIBTEX; some sort of extension to PASCAL's ordinary *reset* and *rewrite* is crucial for our purposes. We shall assume that *name_of_file* is a variable of an appropriate type such that the PASCAL run-time system being used to implement BIBTEX can open a file whose external name is specified by *name_of_file*. BIBTEX does no case conversion for file names.

```

⟨Globals in the outer block 2*⟩ +≡
name_of_file: ↑text_char;
name_length: integer; { this many characters are relevant in name_of_file }
name_ptr: integer; { index variable into name_of_file }

```

38* File opening will be done in C. But we want an auxiliary function to change a BIBTEX string into a C string, to keep string pool stuff out of the C code in *lib/openclose.c*.

```

define no_file_path = -1
⟨Procedures and functions for all file I/O, error messages, and such 3*⟩ +≡
function bib_makecstring(s : str_number): cstring;
var cstr: cstring; i: pool_pointer;
begin cstr ← xmalloc_array(ASCII_code, length(s) + 1);
for i ← 0 to length(s) - 1 do
  begin cstr[i] ← str_pool[str_start[s] + i];
  end;
cstr[length(s)] ← 0; bib_makecstring ← cstr;
exit: end;

```

39* Files can be closed with the PASCAL-H routine '*close(f)*', which should be used when all input or output with respect to *f* has been completed. This makes *f* available to be opened again, if desired; and if *f* was used for output, the *close* operation makes the corresponding external file appear on the user's area, ready to be read.

File closing will be done in C, too.

41* Input from text files is read one line at a time, using a routine called *input_ln*. This function is defined in terms of global variables called *buffer* and *last*. The *buffer* array contains *ASCII_code* values, and *last* is an index into this array marking the end of a line of text. (Occasionally, *buffer* is used for something else, in which case it is copied to a temporary array.)

```

⟨Globals in the outer block 2*⟩ +≡
buf_size: integer; { size of buffer }
buffer: buf_type; { usually, lines of characters being read }
last: buf_pointer; { end of the line just input to buffer }

```

42* The type *buf_type* is used for *buffer*, for saved copies of it, or for scratch work. It's not **packed** because otherwise the program would run much slower on some systems (more than 25 percent slower, for example, on a TOPS-20 operating system). But on systems that are byte-addressable and that have a good compiler, packing *buf_type* would save lots of space without much loss of speed. Other modules that have packable arrays are also marked with a "space savings" index entry.

```

⟨Types in the outer block 22*⟩ +≡
buf_pointer = integer; { an index into a buf_type }
buf_type = ↑ASCII_code; { for various buffers }

```

46* When a buffer overflows, it's time to complain (and then quit).

⟨Procedures and functions for all file I/O, error messages, and such 3*⟩ +≡

```
procedure buffer_overflow;
begin { These are all the arrays of buf_type or that use buf_pointer, that is, they all depend on the
        buf_size value. Therefore we have to reallocate them all at once, even though only one of them has
        overflowed. The alternative seems worse: even more surgery on the program, to have a separate
        variable for each array size instead of the common buf_size. }
  BIB_XRETALLOC_NOSET('buffer', buffer, ASCII_code, buf_size, buf_size + BUF_SIZE);
  BIB_XRETALLOC_NOSET('sv_buffer', sv_buffer, ASCII_code, buf_size, buf_size + BUF_SIZE);
  BIB_XRETALLOC_NOSET('ex_buf', ex_buf, ASCII_code, buf_size, buf_size + BUF_SIZE);
  BIB_XRETALLOC_NOSET('out_buf', out_buf, ASCII_code, buf_size, buf_size + BUF_SIZE);
  BIB_XRETALLOC_NOSET('name_tok', name_tok, buf_pointer, buf_size, buf_size + BUF_SIZE);
  BIB_XRETALLOC('name_sep_char', name_sep_char, ASCII_code, buf_size, buf_size + BUF_SIZE);
end;
```

47* The *input_ln* function brings the next line of input from the specified file into available positions of the buffer array and returns the value *true*, unless the file has already been entirely read, in which case it returns *false* and sets *last* ← 0. In general, the *ASCII_code* numbers that represent the next line of the file are input into *buffer*[0], *buffer*[1], ..., *buffer*[*last* − 1]; and the global variable *last* is set equal to the length of the line. Trailing *white_space* characters are removed from the line (*white_space* characters are explained in the character-set section—most likely they're blanks); thus, either *last* = 0 (in which case the line was entirely blank) or *lex_class*[*buffer*[*last* − 1]] ≠ *white_space*. An overflow error is given if the normal actions of *input_ln* would make *last* > *buf_size*.

Standard PASCAL says that a file should have *eoln* immediately before *eof*, but \LaTeX needs only a weaker restriction: If *eof* occurs in the middle of a line, the system function *eoln* should return a *true* result (even though *f*↑ will be undefined).

⟨Procedures and functions for all file I/O, error messages, and such 3*⟩ +≡

```
function input_ln(var f : alpha_file): boolean; { inputs the next line or returns false }
  label loop_exit;
  begin last ← 0;
  if (eof(f)) then input_ln ← false
  else begin while (¬eoln(f)) do
    begin if (last ≥ buf_size) then buffer_overflow;
    buffer[last] ← xord[getc(f)]; incr(last);
    end;
    vgetc(f); { skip the eol }
    while (last > 0) do { remove trailing white_space }
      if (lex_class[buffer[last − 1]] = white_space) then decr(last)
      else goto loop_exit;
  loop_exit: input_ln ← true;
  end;
end;
```

48* **String handling.** BIB_TE_X uses variable-length strings of seven-bit characters. Since PASCAL does not have a well-developed string mechanism, BIB_TE_X does all its string processing by home-grown (predominantly T_EX's) methods. Unlike T_EX, however, BIB_TE_X does not use a *pool_file* for string storage; it creates its few pre-defined strings at run-time.

The necessary operations are handled with a simple data structure. The array *str_pool* contains all the (seven-bit) ASCII codes in all the strings BIB_TE_X must ever search for (generally identifiers names), and the array *str_start* contains indices of the starting points of each such string. Strings are referred to by integer numbers, so that string number *s* comprises the characters *str_pool*[*j*] for *str_start*[*s*] ≤ *j* < *str_start*[*s* + 1]. Additional integer variables *pool_ptr* and *str_ptr* indicate the number of entries used so far in *str_pool* and *str_start*; locations *str_pool*[*pool_ptr*] and *str_start*[*str_ptr*] are ready for the next string to be allocated. Location *str_start*[0] is unused so that hashing will work correctly.

Elements of the *str_pool* array must be ASCII codes that can actually be printed; i.e., they must have an *xchr* equivalent in the local character set.

```

⟨Globals in the outer block 2*⟩ +≡
str_pool: ↑ASCII_code; { the characters }
str_start: ↑pool_pointer; { the starting pointers }
pool_ptr: pool_pointer; { first unused position in str_pool }
str_ptr: str_number; { start of the current string being created }
str_num: str_number; { general index variable into str_start }
p_ptr1, p_ptr2: pool_pointer; { several procedures use these locally }

```

49* Where *pool_pointer* and *str_number* are pointers into *str_pool* and *str_start*.

```

⟨Types in the outer block 22*⟩ +≡
pool_pointer = integer; { for variables that point into str_pool }
str_number = integer; { for variables that point into str_start }

```

50* These macros send a string in *str_pool* to an output file.

```

define max_pop = 3 {—see the built_in functions section }
define print_pool_str(#) ≡ print_a_pool_str(#) { making this a procedure saves a little space }
define trace_pr_pool_str(#) ≡
  begin out_pool_str(log_file, #);
  end
define log_pr_pool_str(#) ≡ trace_pr_pool_str(#)

```

53* Strings are created by appending character codes to *str_pool*. The macro called *append_char*, defined here, does not check to see if the value of *pool_ptr* has gotten too high; this test is supposed to be made before *append_char* is used.

To test if there is room to append *l* more characters to *str_pool*, we shall write *str_room*(*l*), which aborts BIB_TE_X and gives an error message if there isn't enough room.

```

define append_char(#) ≡ { put ASCII_code # at the end of str_pool }
  begin str_pool[pool_ptr] ← #; incr(pool_ptr);
  end
define str_room(#) ≡ { make sure that the pool hasn't overflowed }
  begin while (pool_ptr + # > pool_size) do pool_overflow;
  end

```

⟨Procedures and functions for all file I/O, error messages, and such 3*⟩ +≡

```

procedure pool_overflow;
  begin BIB_XRETALLOC( `str_pool`, str_pool, ASCII_code, pool_size, pool_size + POOL_SIZE);
  end;

```

58* This procedure copies file name *file_name* into the beginning of *name_of_file*, if it will fit. It also sets the global variable *name_length* to the appropriate value.

⟨Procedures and functions for file-system interacting 58*⟩ ≡

```
procedure start_name(file_name : str_number);
  var p_ptr: pool_pointer; { running index }
  begin free(name_of_file); name_of_file ← xmalloc_array(ASCII_code, length(file_name) + 1);
  name_ptr ← 1; p_ptr ← str_start[file_name];
  while (p_ptr < str_start[file_name + 1]) do
    begin name_of_file[name_ptr] ← chr(str_pool[p_ptr]); incr(name_ptr); incr(p_ptr);
    end;
  name_length ← length(file_name); name_of_file[name_length + 1] ← 0;
end;
```

See also sections 60* and 61*.

This code is used in section 12.

59* Yet another complaint-before-quitting.

⟨Procedures and functions for all file I/O, error messages, and such 3*⟩ +≡

60* This procedure copies file extension *ext* into the array *name_of_file* starting at position *name_length* + 1. It also sets the global variable *name_length* to the appropriate value.

⟨Procedures and functions for file-system interacting 58*⟩ +≡

```
procedure add_extension(ext : str_number);
  var p_ptr: pool_pointer; { running index }
  begin name_ptr ← name_length + 1; p_ptr ← str_start[ext];
  while (p_ptr < str_start[ext + 1]) do
    begin name_of_file[name_ptr] ← chr(str_pool[p_ptr]); incr(name_ptr); incr(p_ptr);
    end;
  name_length ← name_length + length(ext); name_of_file[name_length + 1] ← 0;
end;
```

61* This procedure copies the default logical area name *area* into the array *name_of_file* starting at position 1, after shifting up the rest of the filename. It also sets the global variable *name_length* to the appropriate value.

⟨Procedures and functions for file-system interacting 58*⟩ +≡

64* **The hash table.** All static strings that BIBTEX might have to search for, generally identifiers, are stored and retrieved by means of a fairly standard hash-table algorithm (but slightly altered here) called the method of “coalescing lists” (cf. Algorithm 6.4C in *The Art of Computer Programming*). Once a string enters the table, it is never removed. The actual sequence of characters forming a string is stored in the *str_pool* array.

The hash table consists of the four arrays *hash_next*, *hash_text*, *hash_ilk*, and *ilk_info*. The first array, *hash_next*[*p*], points to the next identifier belonging to the same coalesced list as the identifier corresponding to *p*. The second, *hash_text*[*p*], points to the *str_start* entry for *p*’s string. If position *p* of the hash table is empty, we have *hash_text*[*p*] = 0; if position *p* is either empty or the end of a coalesced hash list, we have *hash_next*[*p*] = *empty*; an auxiliary pointer variable called *hash_used* is maintained in such a way that all locations *p* ≥ *hash_used* are nonempty. The third, *hash_ilk*[*p*], tells how this string is used (as ordinary text, as a variable name, as an *.aux* file command, etc). The fourth, *ilk_info*[*p*], contains information specific to the corresponding *hash_ilk*—for *integer_ilks*: the integer’s value; for *cite_ilks*: a pointer into *cite_list*; for *lc_cite_ilks*: a pointer to a *cite_ilk* string; for *command_ilks*: a constant to be used in a **case** statement; for *bst_fn_ilks*: function-specific information; for *macro_ilks*: a pointer to its definition string; for *control_seq_ilks*: a constant for use in a **case** statement; for all other *ilks* it contains no information. This *ilk*-specific information is set in other parts of the program rather than here in the hashing routine.

```

define hash_is_full ≡ (hash_used = hash_base) { test if all positions are occupied }
define text_ilk = 0 { a string of ordinary text }
define integer_ilk = 1 { an integer (possibly with a minus_sign) }
define aux_command_ilk = 2 { an .aux-file command }
define aux_file_ilk = 3 { an .aux file name }
define bst_command_ilk = 4 { a .bst-file command }
define bst_file_ilk = 5 { a .bst file name }
define bib_file_ilk = 6 { a .bib file name }
define file_ext_ilk = 7 { one of .aux, .bst, .bib, .bbl, or .blg }
define file_area_ilk = 8 { one of texinputs: or texbib: }
define cite_ilk = 9 { a \citation argument }
define lc_cite_ilk = 10 { a \citation argument converted to lower case }
define bst_fn_ilk = 11 { a .bst function name }
define bib_command_ilk = 12 { a .bib-file command }
define macro_ilk = 13 { a .bst macro or a .bib string }
define control_seq_ilk = 14 { a control sequence specifying a foreign character }
define last_ilk = 14 { the same number as on the line above }

```

⟨Types in the outer block 22*⟩ +≡

```

hash_loc = integer; { a location within the hash table }
hash_pointer = integer; { either empty or a hash_loc }
str_ilk = 0 .. last_ilk; { the legal string types }

```

65* ⟨Globals in the outer block 2*⟩ +≡

```

hash_next: ↑hash_pointer; { coalesced-list link }
hash_text: ↑str_number; { pointer to a string }
hash_ilk: ↑str_ilk; { the type of string }
ilk_info: ↑integer; { ilk-specific info }
hash_used: integer; { allocation pointer for hash table }
hash_found: boolean; { set to true if it’s already in the hash table }
dummy_loc: hash_loc; { receives str_lookup value whenever it’s useless }

```

68* Here is the subroutine that searches the hash table for a (string, *str_ilk*) pair, where the string is of length $l \geq 0$ and appears in *buffer*[*j* .. (*j* + *l* - 1)]. If it finds the pair, it returns the corresponding hash-table location and sets the global variable *hash_found* to *true*. Otherwise it sets *hash_found* to *false*, and if the parameter *insert_it* is *true*, it inserts the pair into the hash table, inserts the string into *str_pool* if not previously encountered, and returns its location. Note that two different pairs can have the same string but different *str_ilks*, in which case the second pair encountered, if *insert_it* were *true*, would be inserted into the hash table though its string wouldn't be inserted into *str_pool* because it would already be there.

```

define do_insert  $\equiv$  true  { insert string if not found in hash table }
define dont_insert  $\equiv$  false { don't insert string }
define str_found = 40  { go here when you've found the string }

      else get_aux_command_and_process;
      end;
    trace trace_pr_ln('Finished_reading_the_auxiliary_file(s)');
  ecart
aux_done: last_check_for_aux_errors;

```

This code is used in section 10*.

117* Here we introduce some variables for processing a $\backslash\text{bibdata}$ command. Each element in *bib_list* (except for *bib_list[max_bib_files]*, which is always unused) is a pointer to the appropriate *str_pool* string representing the **.bib** file name. The array *bib_file* contains the corresponding PASCAL **file** variables.

```

  define cur_bib_str ≡ bib_list[bib_ptr] {shorthand for current .bib file}
  define cur_bib_file ≡ bib_file[bib_ptr] {shorthand for current bib_file}
⟨Globals in the outer block 2*⟩ +≡
bib_list: ↑str_number; {the .bib file list}
bib_ptr: bib_number; {pointer for the current .bib file}
num_bib_files: bib_number; {the total number of .bib files}
bib_seen: boolean; {true if we've already seen a \bibdata command}
bib_file: ↑alpha_file; {corresponding file variables}

```

118* Where *bib_number* is the obvious.

```

⟨Types in the outer block 22*⟩ +≡
  bib_number = integer; {gives the bib_list range}

```

121* Here's a procedure we'll need shortly. It prints the name of the current `.bib` file, followed by a *newline*.

(Procedures and functions for all file I/O, error messages, and such **3***) +≡

```

    { Return true if the ext string is at the end of the s string. There are surely far more clever ways to do
      this, but it doesn't matter. }
function str_ends_with(s : str_number; ext : str_number): boolean;
  var i: integer; str_idx, ext_idx: integer; str_char, ext_char: ASCII_code;
  begin str_ends_with ← false;
  if (length(ext) > length(s)) then return; { if extension is longer, they don't match }
  str_idx ← length(s) - 1; ext_idx ← length(ext) - 1;
  while (ext_idx ≥ 0) do
    begin { ≥ so we check the `.` char. }
    str_char ← str_pool[str_start[s] + str_idx]; ext_char ← str_pool[str_start[ext] + ext_idx];
    if (str_char ≠ ext_char) then return;
    decr(str_idx); decr(ext_idx);
    end;
  str_ends_with ← true;
exit: end; { The above is needed because the file name specified in the \bibdata command may or may
  not have the .bib extension. If it does, we don't want to print .bib twice. }
procedure print_bib_name;
  begin print_pool_str(cur_bib_str);
  if ¬str_ends_with(cur_bib_str, s_bib_extension) then print_pool_str(s_bib_extension);
  print_newline;
  end;
procedure log_pr_bib_name;
  begin log_pr_pool_str(cur_bib_str);
  if ¬str_ends_with(cur_bib_str, s_bib_extension) then log_pr_pool_str(s_bib_extension);
  log_pr_newline;
  end;

```

123* Now we add the just-found argument to *bib.list* if it hasn't already been encountered as a `\bibdata` argument and if, after appending the *s_bib.extension* string, the resulting file name can be opened.

⟨ Open a .bib file 123* ⟩ ≡

```

begin if (bib_ptr = max_bib_files) then
  begin { Keep old value of max_bib_files for the last array. }
  BIB_XRETALLOC_NOSET(`bib_list`, bib_list, str_number, max_bib_files,
    max_bib_files + MAX_BIB_FILES); BIB_XRETALLOC_NOSET(`bib_file`, bib_file, alpha_file,
    max_bib_files, max_bib_files + MAX_BIB_FILES); BIB_XRETALLOC(`s_preamble`, s_preamble,
    str_number, max_bib_files, max_bib_files + MAX_BIB_FILES);
  end;
  cur_bib_str ← hash_text[str_lookup(buffer, buf_ptr1, token_len, bib_file_ilk, do_insert)];
  if (hash_found) then { already encountered this as a \bibdata argument }
    open_bibdata_aux_err(`This database file appears more than once: `);

  if (¬kpse_in_name_ok(stringcast(name_of_file + 1)) ∨ ¬a_open_in(cur_bib_file, kpse_bib_format)) then
    open_bibdata_aux_err(`I couldn't open database file`);
  trace trace_pr_pool_str(cur_bib_str); trace trace_pr_pool_str(s_bib_extension);
  trace trace_pr_ln(`is a bibdata file`);
  ecart
  incr(bib_ptr);
end

```

This code is used in section 120.

127* Now we open the file whose name is the just-found argument appended with the *s_bst.extension* string, if possible.

⟨ Open the .bst file 127* ⟩ ≡

```

begin bst_str ← hash_text[str_lookup(buffer, buf_ptr1, token_len, bst_file_ilk, do_insert)];
if (hash_found) then
  begin trace print_bst_name;
  ecart
  confusion(`Already encountered style file`);
  end;
  start_name(bst_str);
  if (¬kpse_in_name_ok(stringcast(name_of_file + 1)) ∨ ¬a_open_in(bst_file, kpse_bst_format)) then
    begin print(`I couldn't open style file`); print bst_name;
    bst_str ← 0; { mark as unused again }
    aux_err_return;
    end;
  if verbose then
    begin print(`The style file: `); print bst_name;
    end
  else begin log_pr(`The style file: `); log_pr bst_name;
  end;
end

```

This code is used in section 126.

128* Print the name of the `.bst` file, followed by a *newline*.

⟨Procedures and functions for all file I/O, error messages, and such 3*⟩ +≡

```
procedure print_bst_name;
```

```
  begin print_pool_str(bst_str); print_pool_str(s_bst_extension); print_newline;
  end;
```

```
procedure log_pr_bst_name;
```

```
  begin log_pr_pool_str(bst_str); log_pr_pool_str(s_bst_extension); log_pr_newline;
  end;
```

129* Here we introduce some variables for processing a `\citation` command. Each element in *cite_list* (except for *cite_list*[*max_cites*], which is always unused) is a pointer to the appropriate *str_pool* string. The cite-key list is kept in order of occurrence with duplicates removed.

```
  define cur_cite_str ≡ cite_list[cite_ptr] {shorthand for the current cite key }
```

⟨Globals in the outer block 2*⟩ +≡

```
cite_list: ↑str_number; { the cite-key list }
```

```
cite_ptr: cite_number; { pointer for the current cite key }
```

```
entry_cite_ptr: cite_number; { cite pointer for the current entry }
```

```
num_cites: cite_number; { the total number of distinct cite keys }
```

```
old_num_cites: cite_number; { set to a previous num_cites value }
```

```
citation_seen: boolean; { true if we've seen a \citation command }
```

```
cite_loc: hash_loc; { the hash-table location of a cite key }
```

```
lc_cite_loc: hash_loc; { and of its lower-case equivalent }
```

```
lc_xcite_loc: hash_loc; { a second lc_cite_loc variable }
```

```
cite_found: boolean; { true if we've already seen this cite key }
```

```
all_entries: boolean; { true if we're to use the entire database }
```

```
all_marker: cite_number; { we put the other entries in cite_list here }
```

130* Where *cite_number* is the obvious.

⟨Types in the outer block 22*⟩ +≡

```
  cite_number = integer; { gives the cite_list range }
```

138* Complain if somebody's got a cite fetish. This procedure is called when were about to add another cite key to *cite_list*. It assumes that *cite_loc* gives the potential cite key's hash table location.

⟨Procedures and functions for all file I/O, error messages, and such 3*⟩ +≡

```
procedure check_cite_overflow(last_cite : cite_number);
```

```
  begin if (last_cite = max_cites) then
```

```
    begin BIB_XRETALLOC_NOSET('cite_list', cite_list, str_number, max_cites,
      max_cites + MAX_CITES);
```

```
    BIB_XRETALLOC_NOSET('type_list', type_list, hash_ptr2, max_cites, max_cites + MAX_CITES);
```

```
    BIB_XRETALLOC_NOSET('entry_exists', entry_exists, boolean, max_cites,
      max_cites + MAX_CITES);
```

```

```

```
  while (last_cite < max_cites) do
```

```
    begin type_list[last_cite] ← empty;
```

```
    cite_info[last_cite] ← any_value; { to appease PASCAL's boolean evaluation }
```

```
    incr(last_cite);
```

```
  end;
```

```
end;
```

```
end;
```

141* We check that this `.aux` file can actually be opened, and then open it.

⟨ Open this `.aux` file 141* ⟩ \equiv

```

begin start_name(cur_aux_str); { extension already there for .aux files }
name_ptr ← name_length + 1; name_of_file[name_ptr] ← 0;
if (¬kpse_in_name_ok(stringcast(name_of_file + 1)) ∨ (¬a_open_in(cur_aux_file,
no_file_path) ∧ ¬a_open_in_with_dirname(cur_aux_file, no_file_path, bib_makecstring(top_lev_str))))
then
begin print('I couldn't open auxiliary file'); print_aux_name; decr(aux_ptr);
aux_err_return;
end;
log_pr('A level-', aux_ptr : 0, ' auxiliary file:'); log_pr_aux_name; cur_aux_line ← 0;
end

```

This code is used in section 140.

151* Here's the outer loop for reading the `.bst` file—it keeps reading and processing `.bst` commands until none left. This is part of the main program; hence, because of the `bst_done` label, there's no conventional **begin - end** pair surrounding the entire module.

```

⟨Read and execute the .bst file 151*⟩ ≡
  if (bst_str = 0) then { there's no .bst file to read }
    goto no_bst_file; { this is a goto so that bst_done is not in a block }
  bst_line_num ← 0; { initialize things }
  bbl_line_num ← 1; { best spot to initialize the output line number }
  buf_ptr2 ← last; { to get the first input line }
  hack1;
  begin if (¬eat_bst_white_space) then { the end of the .bst file }
    hack2;
  get_bst_command_and_process;
  end;
bst_done: a_close(bst_file);
no_bst_file: a_close(bbl_file);

```

This code is used in section 10*.

160* Besides the function classes, we have types based on BIB_TE_X's capacity limitations and one based on what can go into the array `wiz_functions` explained below.

```

⟨Types in the outer block 22*⟩ +≡
  fn_class = 0 .. last_fn_class; { the .bst function classes }
  wiz_fn_loc = integer; { wiz_defined-function storage locations }
  int_ent_loc = integer; { int_entry_var storage locations }
  str_ent_loc = integer; { str_entry_var storage locations }
  str_glob_loc = integer; { str_global_var storage locations }
  field_loc = integer; { individual field storage locations }
  hash_ptr2 = quote_next_fn .. end_of_def; { a special marker or a hash_loc }

```

161.* We store information about the `.bst` functions in arrays the same size as the hash-table arrays and in locations corresponding to their hash-table locations. The two arrays `fn_info` (an alias of `ilk_info` described earlier) and `fn_type` accomplish this: `fn_type` specifies one of the above classes, and `fn_info` gives information dependent on the class.

Six other arrays give the contents of functions: The array `wiz_functions` holds definitions for `wiz_defined` functions—each such function consists of a sequence of pointers to hash-table locations of other functions (with the two special-marker exceptions above); the array `entry_ints` contains the current values of `int_entry_vars`; the array `entry_strs` contains the current values of `str_entry_vars`; an element of the array `global_strs` contains the current value of a `str_global_var` if the corresponding `glb_str_ptr` entry is empty, otherwise the nonempty entry is a pointer to the string; and the array `field_info`, for each field of each entry, contains either a pointer to the string or the special value `missing`.

The array `global_strs` isn't packed (that is, it isn't `array ... of packed array ...`) to increase speed on some systems; however, on systems that are byte-addressable and that have a good compiler, packing `global_strs` would save lots of space without much loss of speed.

```
define fn_info ≡ ilk_info { an alias used with functions }
```

```
define missing = empty { a special pointer for missing fields }
```

```
<Globals in the outer block 2*> +≡
```

```
fn_loc: hash_loc; { the hash-table location of a function }
```

```
wiz_loc: hash_loc; { the hash-table location of a wizard function }
```

```
literal_loc: hash_loc; { the hash-table location of a literal function }
```

```
macro_name_loc: hash_loc; { the hash-table location of a macro name }
```

```
macro_def_loc: hash_loc; { the hash-table location of a macro definition }
```

```
fn_type: ↑fn_class;

```

```
crossref_num: field_loc; { the number given to crossref }
```

```
no_fields: boolean; { used for tr_printing entry information }
```

187* This recursive function reads and stores the list of functions (separated by *white_space* characters or ends-of-line) that define this new function, and reads a *right_brace*.

⟨Procedures and functions for input scanning 83⟩ +≡

```
procedure scan_fn_def(fn_hash_loc : hash_loc);
  label next_token, exit;
  type fn_def_loc = integer; { for a single wiz_defined-function }
  var singl_function: ↑hash_ptr2; single_fn_space: integer;
      { space allocated for this singl_function instance }
      single_ptr: fn_def_loc; { next storage location for this definition }
      copy_ptr: fn_def_loc; { dummy variable }
      end_of_num: buf_pointer; { the end of an implicit function's name }
      impl_fn_loc: hash_loc; { an implicit function's hash-table location }
  begin single_fn_space ← SINGLE_FN_SPACE;
  singl_function ← XTALLOC(single_fn_space + 1, hash_ptr2); eat_bst_white_and_eof_check(`function`);
  single_ptr ← 0;
  while (scan_char ≠ right_brace) do
    begin ⟨Get the next function of the definition 189⟩;
    next_token: eat_bst_white_and_eof_check(`function`);
    end;
  ⟨Complete this function's definition 200*⟩;
  incr(buf_ptr2); { skip over the right_brace }
  exit: libc_free(singl_function);
end;
```

188* This macro inserts a hash-table location (or one of the two special markers *quote_next_fn* and *end_of_def*) into the *singl_function* array, which will later be copied into the *wiz_functions* array.

```
define insert_fn_loc(#) ≡
  begin singl_function[single_ptr] ← #;
  if (single_ptr = single_fn_space) then
    begin BIB_XRETALLOC(`singl_function`, singl_function, hash_ptr2, single_fn_space,
      single_fn_space + SINGLE_FN_SPACE);
    end;
  incr(single_ptr);
end
```

⟨Procedures and functions for all file I/O, error messages, and such 3*⟩ +≡

198* This procedure takes the integer *int*, copies the appropriate *ASCII_code* string into *int_buf* starting at *int_begin*, and sets the **var** parameter *int_end* to the first unused *int_buf* location. The ASCII string will consist of decimal digits, the first of which will not be a 0 if the integer is nonzero, with a prepended minus sign if the integer is negative.

define *int* \equiv *the_int*

\langle Procedures and functions for handling numbers, characters, and strings 54 \rangle \equiv
procedure *int_to_ASCII*(*int* : *integer*; **var** *int_buf* : *buf_type*; *int_begin* : *buf_pointer*;
 var *int_end* : *buf_pointer*);
var *int_ptr*, *int_xptr*: *buf_pointer*; { pointers into *int_buf* }
 int_tmp_val: *ASCII_code*; { the temporary element in an exchange }
begin *int_ptr* \leftarrow *int_begin*;
if (*int* < 0) **then** { add the *minus_sign* and use the absolute value }
 begin *append_int_char*(*minus_sign*); *int* \leftarrow $-int$;
 end;
int_xptr \leftarrow *int_ptr*;
repeat { copy digits into *int_buf* }
 append_int_char("0" + (*int mod* 10)); *int* \leftarrow *int div* 10;
until (*int* = 0);
int_end \leftarrow *int_ptr*; { set the string length }
decr(*int_ptr*);
while (*int_xptr* < *int_ptr*) **do** { and reorder (flip) the digits }
 begin *int_tmp_val* \leftarrow *int_buf*[*int_xptr*]; *int_buf*[*int_xptr*] \leftarrow *int_buf*[*int_ptr*];
 int_buf[*int_ptr*] \leftarrow *int_tmp_val*; *decr*(*int_ptr*); *incr*(*int_xptr*);
 end
end;

200* Now we add the *end_of_def* special marker, make sure this function will fit into *wiz_functions*, and put it there.

\langle Complete this function's definition 200* \rangle \equiv
begin *insert_fn_loc*(*end_of_def*); { add special marker ending the definition }
while (*single_ptr* + *wiz_def_ptr* > *wiz_fn_space*) **do**
 begin *BIB_XRETALLOC*('wiz_functions', *wiz_functions*, *hash_ptr2*, *wiz_fn_space*,
 wiz_fn_space + *WIZ_FN_SPACE*);
 end;
fn_info[*fn_hash_loc*] \leftarrow *wiz_def_ptr*; { pointer into *wiz_functions* }
copy_ptr \leftarrow 0;
while (*copy_ptr* < *single_ptr*) **do** { make this function official }
 begin *wiz_functions*[*wiz_def_ptr*] \leftarrow *singl_function*[*copy_ptr*]; *incr*(*copy_ptr*); *incr*(*wiz_def_ptr*);
 end;
end

This code is used in section 187*.

216* Here we insert the just found *str_global_var* name into the hash table, record it as a *str_global_var*, set its pointer into *global_strs*, and initialize its value there to the null string.

```

define end_of_string = invalid_code { this illegal ASCII_code ends a string }
⟨Insert a str_global_var into the hash table 216*⟩ ≡
begin trace trace_pr_token; trace_pr_ln(`is_a_string_global-variable`);
ecart
lower_case(buffer, buf_ptr1, token_len); { ignore case differences }
fn_loc ← str_lookup(buffer, buf_ptr1, token_len, bst_fn_ilk, do_insert);
check_for_already_seen_function(fn_loc); fn_type[fn_loc] ← str_global_var;
fn_info[fn_loc] ← num_glb_strs; { pointer into global_strs }
if (num_glb_strs = max_glob_strs) then
  begin BIB_XRETALLOC_NOSET(`glb_str_ptr`, glb_str_ptr, str_number, max_glob_strs,
    max_glob_strs + MAX_GLOB_STRS); BIB_XRETALLOC_STRING(`global_strs`, global_strs,
    glob_str_size, max_glob_strs, max_glob_strs + MAX_GLOB_STRS);
  BIB_XRETALLOC(`glb_str_end`, glb_str_end, integer, max_glob_strs,
    max_glob_strs + MAX_GLOB_STRS); str_glb_ptr ← num_glb_strs;
  while (str_glb_ptr < max_glob_strs) do { make new str_global_vars empty }
    begin glb_str_ptr[str_glb_ptr] ← 0; glb_str_end[str_glb_ptr] ← 0; incr(str_glb_ptr);
    end;
  end;
incr(num_glb_strs);
end

```

This code is used in section 215.

219* These global variables are used while reading the `.bib` file(s). The elements of `type_list`, which indicate an entry's type (book, article, etc.), point either to a `hash_loc` or are one of two special markers: `empty`, from which `hash_base = empty + 1` was defined, means we haven't yet encountered the `.bib` entry corresponding to this cite key; and `undefined` means we've encountered it but it had an unknown entry type. Thus the array `type_list` is of type `hash_ptr2`, also defined earlier. An element of the boolean array `entry_exists` whose corresponding entry in `cite_list` gets overwritten (which happens only when `all_entries` is `true`) indicates whether we've encountered that entry of `cite_list` while reading the `.bib` file(s); this information is unused for entries that aren't (or more precisely, that have no chance of being) overwritten. When we're reading the database file, the array `cite_info` contains auxiliary information for `cite_list`. Later, `cite_info` will become `sorted_cites`, and this dual role imposes the (not-very-imposing) restriction `max_strings ≥ max_cites`.

```

⟨Globals in the outer block 2*⟩ +=
bib_line_num: integer; { line number of the .bib file }
entry_type_loc: hash_loc; { the hash-table location of an entry type }
type_list: ↑hash_ptr2;
type_exists: boolean; { true if this entry type is .bst-defined }
entry_exists: ↑boolean;

ecart
⟨Final initialization for processing the entries 276⟩;
read_completed ← true;
end

```

This code is used in section 211.

226* Complain if somebody's got a field fetish.

⟨Procedures and functions for all file I/O, error messages, and such 3*⟩ +≡

```
procedure check_field_overflow(total_fields : integer);
  var f_ptr : field_loc; start_fields : field_loc;
  begin if (total_fields > max_fields) then
    begin start_fields ← max_fields;
      BIB_XRETALLOC(`field_info`, field_info, str_number, max_fields, total_fields + MAX_FIELDS);
      { Initialize to missing. }
    for f_ptr ← start_fields to max_fields - 1 do
      begin field_info[f_ptr] ← missing;
    end;
  end;
end;
```

242* The `preamble` command lets a user have T_EX stuff inserted (by the standard styles, at least) directly into the .bbl file. It is intended primarily for allowing T_EX macro definitions used within the bibliography entries (for better sorting, for example). One `preamble` command per .bib file should suffice.

A `preamble` command has either braces or parentheses as outer delimiters. Inside is the preamble string, which has the same syntax as a field value: a nonempty list of field tokens separated by *concat_chars*. There are three types of field tokens—nonnegative numbers, macro names, and delimited strings.

This module does all the scanning (that's not subcontracted), but the .bib-specific scanning function *scan_and_store_the_field_value_and_eat_white* actually stores the value.

⟨Process a `preamble` command 242*⟩ ≡

```
begin if (preamble_ptr = max_bib_files) then
  begin { Keep old value of max_bib_files for the last array. }
  BIB_XRETALLOC_NOSET(`bib_list`, bib_list, str_number, max_bib_files,
    max_bib_files + MAX_BIB_FILES); BIB_XRETALLOC_NOSET(`bib_file`, bib_file, alpha_file,
    max_bib_files, max_bib_files + MAX_BIB_FILES); BIB_XRETALLOC(`s_preamble`, s_preamble,
    str_number, max_bib_files, max_bib_files + MAX_BIB_FILES);
  end;
  eat_bib_white_and_eof_check;
  if (scan_char = left_brace) then right_outer_delim ← right_brace
  else if (scan_char = left_paren) then right_outer_delim ← right_paren
    else bib_one_of_two_expected_err(left_brace, left_paren);
  incr(buf_ptr2); { skip over the left-delimiter }
  eat_bib_white_and_eof_check; store_field ← true;
  if (¬scan_and_store_the_field_value_and_eat_white) then return;
  if (scan_char ≠ right_outer_delim) then
    bib_err(`Missing_`, xchr[right_outer_delim], `_in_preamble_command`);
  incr(buf_ptr2); { skip over the right_outer_delim }
  return;
end
```

This code is used in section 239.

251* Now we come to the stuff that actually accumulates the field value to be stored. This module copies a character into *field_vl_str* if it will fit; since it's so low level, it's implemented as a macro.

```
define copy_char(#) ≡
  begin { We don't always increment by 1, so have to check ≥. }
  if (field_end ≥ buf_size) then
    begin log_pr('Field_filled_up_at_#, ', _reallocating.); log_pr_newline;
    buffer_overflow; { reallocates all buf_size buffers }
    end;
  field_vl_str[field_end] ← #; incr(field_end);
end
```

263* And here, an entry.

⟨Store the field value for a database entry 263*⟩ ≡

```
begin field_ptr ← entry_cite_ptr * num_fields + fn_info[field_name_loc];
if (field_ptr ≥ max_fields) then confusion('field_info_index_is_out_of_range');
if (field_info[field_ptr] ≠ missing) then
  begin print('Warning--I'm_ignoring_'); print_pool_str(cite_list[entry_cite_ptr]);
  print('`s_extra`'); print_pool_str(hash_text[field_name_loc]); bib_warn_newline('`_field`');
  end
else begin { the field was empty, store its new value }
  field_info[field_ptr] ← hash_text[field_val_loc];
  if ((fn_info[field_name_loc] = crossref_num) ∧ (¬all_entries)) then
    ⟨Add or update a cross reference on cite_list if necessary 264⟩;
  end;
end
```

This code is used in section 261.

265* This procedure adds (or restores) to *cite_list* a cite key; it is called only when *all_entries* is *true* or when adding cross references, and it assumes that *cite_loc* and *lc_cite_loc* are set. It also increments its argument.

⟨Procedures and functions for handling numbers, characters, and strings 54⟩ +≡

```
procedure add_database_cite(var new_cite : cite_number);
  begin check_cite_overflow(new_cite); { make sure this cite will fit }
  check_field_overflow(num_fields * (new_cite + 1)); cite_list[new_cite] ← hash_text[cite_loc];
  ilk_info[cite_loc] ← new_cite; ilk_info[lc_cite_loc] ← cite_loc; incr(new_cite);
end;
```

277* Now we update any entry (here called a *child* entry) that cross referenced another (here called a *parent* entry); this cross referencing occurs when the child's **crossref** field (value) consists of the parent's database key. To do the update, we replace the child's *missing* fields by the corresponding fields of the parent. Also, we make sure the **crossref** field contains the case-correct version. Finally, although it is technically illegal to nest cross references, and although we give a warning (a few modules hence) when someone tries, we do what we can to accommodate the attempt.

⟨Add cross-reference information 277*⟩ ≡

```

begin if ((num_cites - 1) * num_fields + crossref_num ≥ max_fields) then
  confusion(`field_info_index_is_out_of_range`);
cite_ptr ← 0;
while (cite_ptr < num_cites) do
  begin field_ptr ← cite_ptr * num_fields + crossref_num;
  if (field_info[field_ptr] ≠ missing) then
    if (find_cite_locs_for_this_cite_key(field_info[field_ptr])) then
      begin cite_loc ← ilk_info[lc_cite_loc]; field_info[field_ptr] ← hash_text[cite_loc];

    begin x_entry_strs(str_ent_ptr)(0) ← end_of_string; incr(str_ent_ptr);
    end;
  end

```

This code is used in section 276.

290* **Executing the style file.** This part of the program produces the output by executing the `.bst-` file commands `execute`, `iterate`, `reverse`, and `sort`. To do this it uses a stack (consisting of the two arrays `lit_stack` and `lit_stk_type`) for storing literals, a buffer `ex_buf` for manipulating strings, and an array `sorted_cites` for holding pointers to the sorted cite keys (`sorted_cites` is an alias of `cite_info`).

```

⟨Globals in the outer block 2*⟩ +=
lit_stack: ↑integer; { the literal function stack }
lit_stk_type: ↑stk_type; { their corresponding types }
lit_stk_ptr: lit_stk_loc; { points just above the top of the stack }
cmd_str_ptr: str_number; { stores value of str_ptr during execution }
ent_chr_ptr: 0 .. ent_str_size; { points at a str_entry_var character }
glob_chr_ptr: 0 .. glob_str_size; { points at a str_global_var character }
ex_buf: buf_type; { a buffer for manipulating strings }
ex_buf_ptr: buf_pointer; { general ex_buf location }
ex_buf_length: buf_pointer; { the length of the current string in ex_buf }
out_buf: buf_type; { the .bbl output buffer }
out_buf_ptr: buf_pointer; { general out_buf location }
out_buf_length: buf_pointer; { the length of the current string in out_buf }
mess_with_entries: boolean; { true if functions can use entry info }
sort_cite_ptr: cite_number; { a loop index for the sorted cite keys }
sort_key_num: str_ent_loc; { index for the str_entry_var sort.key$ }
brace_level: integer; { the brace nesting depth within a string }

```

291* Where `lit_stk_loc` is a stack location, and where `stk_type` gives one of the three types of literals (an integer, a string, or a function) or a special marker. If a `lit_stk_type` element is a `stk_int` then the corresponding `lit_stack` element is an integer; if a `stk_str`, then a pointer to a `str_pool` string; and if a `stk_fn`, then a pointer to the function's hash-table location. However, if the literal should have been a `stk_str` that was the value of a field that happened to be `missing`, then the special value `stk_field_missing` goes on the stack instead; its corresponding `lit_stack` element is a pointer to the field-name's string. Finally, `stk_empty` is the type of a literal popped from an empty stack.

```

define stk_int = 0 { an integer literal }
define stk_str = 1 { a string literal }
define stk_fn = 2 { a function literal }
define stk_field_missing = 3 { a special marker: a field value was missing }
define stk_empty = 4 { another: the stack was empty when this was popped }
define last_lit_type = 4 { the same number as on the line above }

```

```

⟨Types in the outer block 22*⟩ +=
lit_stk_loc = integer; { the stack range }
stk_type = 0 .. last_lit_type; { the literal types }

```

301* The function *less_than* compares the two `sort.key$`s indirectly pointed to by its arguments and returns *true* if the first argument's `sort.key$` is lexicographically less than the second's (that is, alphabetically earlier). In case of ties the function compares the indices *arg1* and *arg2*, which are assumed to be different, and returns *true* if the first is smaller. This function uses *ASCII_codes* to compare, so it might give "interesting" results when handling nonletters.

```
define compare_return(#) ≡
    begin { the compare is finished }
    less_than ← #; return;
end
```

⟨Procedures and functions for handling numbers, characters, and strings 54⟩ +≡

```
function less_than(arg1, arg2 : cite_number): boolean;
label exit;

```

See also sections 309, 312, 314, 315, 316, 317, 318, 320, 322*, and 342.

This code is used in section 12.

322* This procedure adds to the output buffer the given string in *str_pool*. It assumes the global variable *out_buf_length* gives the length of the current string in *out_buf*, and thus also gives the location for the next character. If there are enough characters present in the output buffer, it writes one or more lines out to the .bbl file. It breaks a line only at a *white_space* character, and when it does, it adds two *spaces* to the next output line.

⟨Procedures and functions for style-file function execution 307*⟩ +≡

```
procedure add_out_pool(p_str : str_number);
  label loop1_exit, loop2_exit;
  var break_ptr: buf_pointer; { the first character following the line break }
      end_ptr: buf_pointer; { temporary end-of-buffer pointer }
      break_pt_found: boolean; { a suitable white_space character }
      unbreakable_tail: boolean; { as it contains no white_space character }
  begin p_ptr1 ← str_start[p_str]; p_ptr2 ← str_start[p_str + 1];
  while (out_buf_length + (p_ptr2 - p_ptr1) > buf_size) do buffer_overflow;
  out_buf_ptr ← out_buf_length;
  while (p_ptr1 < p_ptr2) do
    begin { copy characters into the buffer }
      out_buf[out_buf_ptr] ← str_pool[p_ptr1]; incr(p_ptr1); incr(out_buf_ptr);
    end;
    out_buf_length ← out_buf_ptr; unbreakable_tail ← false;
  while ((out_buf_length > max_print_line) ∧ (¬unbreakable_tail)) do ⟨Break that line 323⟩;
  end;
```

327* This module pushes the string given by the field onto the literal stack unless it's *missing*, in which case it pushes a special value onto the stack.

⟨Execute a field 327*⟩ ≡

```
begin if (¬mess_with_entries) then bst_cant_mess_with_entries_print
else begin field_ptr ← cite_ptr * num_fields + fn_info[ex_fn_loc];
  if (field_ptr ≥ max_fields) then confusion(`field_info_index_is_out_of_range`);
  if (field_info[field_ptr] = missing) then push_lit_stk(hash_text[ex_fn_loc], stk_field_missing)
  else push_lit_stk(field_info[field_ptr], stk_str);
  end
end
```

This code is used in section 325.

329* This module adds the string given by a *str_entry_var* to *str_pool* via the execution buffer and pushes it onto the literal stack.

⟨Execute a *str_entry_var* 329*⟩ ≡

```
begin if (¬mess_with_entries) then bst_cant_mess_with_entries_print
else begin str_ent_ptr ← cite_ptr * num_ent_strs + fn_info[ex_fn_loc];
  ex_buf_ptr ← 0; { also serves as ent_chr_ptr }
  while (x_entry_strs(str_ent_ptr)(ex_buf_ptr) ≠ end_of_string) do { copy characters into the buffer }
    append_ex_buf_char(x_entry_strs(str_ent_ptr)(ex_buf_ptr));
    ex_buf_length ← ex_buf_ptr; add_pool_buf_and_push; { push this string onto the stack }
  end;
end
```

This code is used in section 325.

330* This module pushes the string given by a *str_global_var* onto the literal stack, but it copies the string to *str_pool* (character by character) only if it has to—it *doesn't* have to if the string is static (that is, if the string isn't at the top, temporary part of the string pool).

⟨Execute a *str_global_var* 330*⟩ ≡

```

begin str_glb_ptr ← fn_info[ex_fn_loc];
if (glb_str_ptr[str_glb_ptr] > 0) then { we're dealing with a static string }
  push_lit_stk(glb_str_ptr[str_glb_ptr], stk_str)
else begin str_room(glb_str_end[str_glb_ptr]); glob_chr_ptr ← 0;
  while (glob_chr_ptr < glb_str_end[str_glb_ptr]) do { copy the string }
    begin append_char(x_global_strs(str_glb_ptr)(glob_chr_ptr)); incr(glob_chr_ptr);
    end;
  push_lit_stk(make_string, stk_str); { and push it onto the stack }
  end;
end

```

This code is used in section 325.

334* It's time for us to insert more pre-defined strings into *str_pool* (and thus the hash table) and to insert the *built_in* functions into the hash table. The strings corresponding to these functions should contain no upper-case letters, and they must all be exactly *longest_pds* characters long. The *build_in* routine (to appear shortly) does the work.

Important note: These pre-definitions must not have any glitches or the program may bomb because the *log_file* hasn't been opened yet.

(Pre-define certain strings 75) +=

```

388* This module removes all leading *white_space* (and *sep_chars*), and trailing *white_space* (and *sep_chars*) and *commas*. It complains for each trailing *comma*.

```

⟨Remove leading and trailing junk, complaining if necessary 388*⟩ ≡
  begin while (ex_buf_ptr > ex_buf_xptr) do { now remove trailing stuff }
    case (lex_class[ex_buf[ex_buf_ptr - 1]]) of
      white_space, sep_char: decr(ex_buf_ptr);
    othercases if (ex_buf[ex_buf_ptr - 1] = comma) then
      begin print(^Name_, pop_lit2 : 0, ^in_); print_pool_str(pop_lit3);
        print(^_has_a_comma_at_the_end^); bst_ex_warn_print; decr(ex_buf_ptr);
      end
      else goto loop1_exit
    endcases;
  loop1_exit: end

```

This code is used in section 387.

438* This module finds the substring as described in the last section, and slides it into place in the string pool, if necessary.

```

⟨Form the appropriate substring 438*⟩ ≡
  begin if (pop_lit2 > 0) then
    begin if (pop_lit1 > sp_length - (pop_lit2 - 1)) then pop_lit1 ← sp_length - (pop_lit2 - 1);
      sp_ptr ← str_start[pop_lit3] + (pop_lit2 - 1); sp_end ← sp_ptr + pop_lit1;
    if (pop_lit2 = 1) then
      if (pop_lit3 ≥ cmd_str_ptr) then { no shifting—merely change pointers }
        begin str_start[pop_lit3 + 1] ← sp_end; unflush_string; incr(lit_stk_ptr); return;
        end;
      end
    else { -ex_buf_length ≤ pop_lit2 < 0 }
    begin pop_lit2 ← -pop_lit2;
    if (pop_lit1 > sp_length - (pop_lit2 - 1)) then pop_lit1 ← sp_length - (pop_lit2 - 1);
      sp_end ← str_start[pop_lit3 + 1] - (pop_lit2 - 1); sp_ptr ← sp_end - pop_lit1;
    end; str_room(sp_end - sp_ptr);
    while (sp_ptr < sp_end) do { shift the substring }
      begin append_char(str_pool[sp_ptr]); incr(sp_ptr);
      end;
    push_lit_stk(make_string, stk_str); { and push it onto the stack }
    end

```

This code is used in section 437.

444* This module finds the prefix as described in the last section, and appends any needed matching *right_braces*.

```

⟨Form the appropriate prefix 444*⟩ ≡
  begin sp_ptr ← str_start[pop_lit2]; sp_end ← str_start[pop_lit2 + 1]; { this may change }
  ⟨Scan the appropriate number of characters 445⟩;
  str_room(sp_brace_level + sp_end - sp_ptr);
  if (pop_lit2 ≥ cmd_str_ptr) then { no shifting—merely change pointers }
    pool_ptr ← sp_end
  else while (sp_ptr < sp_end) do { shift the substring }
    begin append_char(str_pool[sp_ptr]); incr(sp_ptr);
    end;
  while (sp_brace_level > 0) do { add matching right_braces }
    begin append_char(right_brace); decr(sp_brace_level);
    end;
  push_lit_stk(make_string, stk_str); { and push it onto the stack }
  end

```

This code is used in section 443.

459* This prints information gathered while reading the .bst and .bib files.

```

⟨Print entry information 459*⟩ ≡
  begin trace_pr(‘,entry-type’);
  if (type_list[cite_ptr] = undefined) then trace_pr(‘unknown’);
  else if (type_list[cite_ptr] = empty) then trace_pr(‘---no_type_found’);
    else trace_pr_pool_str(hash_text[type_list[cite_ptr]]);

    must have one remaining argument. }
if (optind + 1 ≠ argc) then
    begin write_ln(stderr, my_name, ^: Need exactly one file argument.^); usage(my_name);
    end;
end;

```

This code is used in section 10*.

468* Here is the first of the options we allow.

```

⟨Define the option table 468*⟩ ≡
    current_option ← 0; long_options[0].name ← ^terse^; long_options[0].has_arg ← 0;
    long_options[0].flag ← address_of(verbose); long_options[0].val ← 0; incr(current_option);

```

See also sections 471*, 474*, 475*, and 476*.

This code is used in section 467*.

469* The global variable *verbose* determines whether or not we print progress information.

```

⟨Globals in the outer block 2*⟩ +≡
verbose: c_int_type;

```

470* Start off *true*, to match the default behavior.

```

⟨Initialize the option variables 470*⟩ ≡
    verbose ← true;

```

See also section 473*.

This code is used in section 467*.

471* Here is an option to change the minimum number of cross-refs required for automatic *cite_list* inclusion.

```
⟨Define the option table 468*⟩ +≡
  long_options[current_option].name ← `min-crossrefs`; long_options[current_option].has_arg ← 1;
  long_options[current_option].flag ← 0; long_options[current_option].val ← 0; incr(current_option);
```

472* ⟨Globals in the outer block 2*⟩ +≡
min_crossrefs: integer;

473* Set *min_crossrefs* to two by default, so we match the documentation (`btldoc.tex`).

```
⟨Initialize the option variables 470*⟩ +≡
  min_crossrefs ← 2;
```

474* One of the standard options.

```
⟨Define the option table 468*⟩ +≡
  long_options[current_option].name ← `help`; long_options[current_option].has_arg ← 0;
  long_options[current_option].flag ← 0; long_options[current_option].val ← 0; incr(current_option);
```

475* Another of the standard options.

```
⟨Define the option table 468*⟩ +≡
  long_options[current_option].name ← `version`; long_options[current_option].has_arg ← 0;
  long_options[current_option].flag ← 0; long_options[current_option].val ← 0; incr(current_option);
```

476* An element with all zeros always ends the list.

```
⟨Define the option table 468*⟩ +≡
  long_options[current_option].name ← 0; long_options[current_option].has_arg ← 0;
  long_options[current_option].flag ← 0; long_options[current_option].val ← 0;
```

477* Determine *ent_str_size*, *glob_str_size*, and *max_strings* from the environment, configuration file, or default value. Set *hash_size* ← *max_strings*, but not less than *HASH_SIZE*.

setup_bound_var stuff adapted from `tex.ch`.

```
define setup_bound_var(#) ≡ bound_default ← #; setup_bound_var_end
```

```
define setup_bound_var_end(#) ≡ bound_name ← #; setup_bound_var_end_end
```

```
define setup_bound_var_end_end(#) ≡ setup_bound_variable(address_of(#), bound_name, bound_default);
```

```
  if # < bound_default then # ← bound_default
```

```
⟨Procedures and functions for about everything 12⟩ +≡
```

```
procedure setup_params;
```

```
  var bound_default: integer; { for setup }
```

```
  bound_name: const_cstring; { for setup }
```

```
  begin kpse_set_program_name(argv[0], `bibtex`);
```

```
  setup_bound_var(ENT_STR_SIZE)(`ent_str_size`)(ent_str_size);
```

```
  setup_bound_var(GLOB_STR_SIZE)(`glob_str_size`)(glob_str_size);
```

```
  setup_bound_var(MAX_STRINGS)(`max_strings`)(max_strings);
```

```
  setup_bound_var(MAX_PRINT_LINE)(`max_print_line`)(max_print_line);
```

```
  hash_size ← max_strings;
```

```
  if hash_size < HASH_SIZE then hash_size ← HASH_SIZE;
```

```
  hash_max ← hash_size + hash_base - 1; end_of_def ← hash_max + 1; undefined ← hash_max + 1;
```

```
  end;
```

478* We use the algorithm from Knuth's `primes.web` to compute `hash_prime` as the smallest prime number not less than 85% of `hash_size` (and ≥ 128).

```

define primes  $\equiv$  hash_next { array holding the first k primes }
define mult  $\equiv$  hash_text { array holding odd multiples of the first o primes }
⟨ Procedures and functions for about everything 12 ⟩  $\equiv$ 
procedure compute_hash_prime;
  var hash_want: integer; { 85% of hash_size }
      k: integer; { number of prime numbers  $p_i$  in primes }
      j: integer; { a prime number candidate }
      o: integer; { number of odd multiples of primes in mult }
      square: integer; {  $p_o^2$  }
      n: integer; { loop index }
      j_prime: boolean; { is j a prime? }

          incr(n);
        end;
      until j_prime;
      incr(k); hash_prime  $\leftarrow$  j; primes[k]  $\leftarrow$  hash_prime;
    end;
  end;

```

479* Index. Here is where you can find all uses of each identifier in the program, with underlined entries pointing to where the identifier was defined. If the identifier is only one letter long, however, you get to see only the underlined entries. All references are to section numbers instead of page numbers.

This index also lists a few error messages and other aspects of the program that you might want to look up some day. For example, the entry for “system dependencies” lists all sections that should receive special attention from people who are installing T_EX in a new operating environment. A list of various things that can’t happen appears under “this can’t happen”.

The following sections were changed by the change file: [1](#), [2](#), [3](#), [4](#), [10](#), [13](#), [14](#), [15](#), [16](#), [17](#), [22](#), [23](#), [27](#), [28](#), [32](#), [33](#), [37](#), [38](#), [39](#), [41](#), [42](#), [46](#), [47](#), [48](#), [49](#), [50](#), [53](#), [58](#), [59](#), [60](#), [61](#), [64](#), [65](#), [68](#), [70](#), [71](#), [73](#), [77](#), [97](#), [100](#), [101](#), [102](#), [106](#), [108](#), [110](#), [117](#), [118](#), [121](#), [123](#), [127](#), [128](#), [129](#), [130](#), [138](#), [141](#), [151](#), [160](#), [161](#), [187](#), [188](#), [198](#), [200](#), [216](#), [219](#), [223](#), [226](#), [242](#), [251](#), [263](#), [265](#), [277](#), [279](#), [285](#), [287](#), [288](#), [290](#), [291](#), [301](#), [307](#), [322](#), [327](#), [329](#), [330](#), [334](#), [337](#), [344](#), [357](#), [359](#), [388](#), [438](#), [444](#), [459](#), [460](#), [462](#), [467](#), [468](#), [469](#), [470](#), [471](#), [472](#), [473](#), [474](#), [475](#), [476](#), [477](#), [478](#), [479](#).

- ⟨ Add cross-reference information 277* ⟩ Used in section 276.
- ⟨ Add extensions and open files 106* ⟩ Used in section 103.
- ⟨ Add or update a cross reference on *cite_list* if necessary 264 ⟩ Used in section 263*.
- ⟨ Add the *period* (it's necessary) and push 362 ⟩ Used in section 361.
- ⟨ Add the *period*, if necessary, and push 361 ⟩ Used in section 360.
- ⟨ Add up the *char_widths* in this string 451 ⟩ Used in section 450.
- ⟨ Assign to a *str_entry_var* 357* ⟩ Used in section 354.
- ⟨ Assign to a *str_global_var* 359* ⟩ Used in section 354.
- ⟨ Assign to an *int_entry_var* 355 ⟩ Used in section 354.
- ⟨ Assign to an *int_global_var* 358 ⟩ Used in section 354.
- ⟨ Break that line 323 ⟩ Used in section 322*.
- ⟨ Break that unbreakably long line 324 ⟩ Used in section 323.
- ⟨ Check and insert the quoted function 193 ⟩ Used in section 192.
- ⟨ Check for a database key of interest 267 ⟩ Used in section 266.
- ⟨ Check for a duplicate or **crossref**-matching database key 268 ⟩ Used in section 267.
- ⟨ Check for entire database inclusion (and thus skip this cite key) 134 ⟩ Used in section 133.
- ⟨ Check the **execute**-command argument token 179 ⟩ Used in section 178.
- ⟨ Check the **iterate**-command argument token 204 ⟩ Used in section 203.
- ⟨ Check the **reverse**-command argument token 213 ⟩ Used in section 212.
- ⟨ Check the “constant” values for consistency 17*, 302 ⟩ Used in section 13*.
- ⟨ Check the cite key 133 ⟩ Used in section 132.
- ⟨ Check the macro name 207 ⟩ Used in section 206.
- ⟨ Check the special character (and **return**) 398 ⟩ Used in section 397.
- ⟨ Check the *wiz_defined* function name 182 ⟩ Used in section 181.
- ⟨ Cite seen, don't add a cite key 135 ⟩ Used in section 133.
- ⟨ Cite unseen, add a cite key 136 ⟩ Used in section 133.
- ⟨ Clean up and leave 455 ⟩ Used in section 10*.
- ⟨ Compiler directives 11 ⟩ Used in section 10*.
- ⟨ Complain about a nested cross reference 282 ⟩ Used in section 279*.
- ⟨ Complain about missing entries whose cite keys got overwritten 286 ⟩ Used in section 283.
- ⟨ Complete this function's definition 200* ⟩ Used in section 187*.
- ⟨ Compute the hash code *h* 69 ⟩ Used in section 68*.
- ⟨ Concatenate the two strings and push 351 ⟩ Used in section 350.
- ⟨ Concatenate them and push when *pop_lit1*, *pop_lit2* < *cmd_str_ptr* 353 ⟩ Used in section 352.
- ⟨ Concatenate them and push when *pop_lit2* < *cmd_str_ptr* 352 ⟩ Used in section 351.
- ⟨ Constants in the outer block 14*, 333 ⟩ Used in section 10*.
- ⟨ Convert a noncontrol sequence 375 ⟩ Used in section 371.
- ⟨ Convert a special character 371 ⟩ Used in section 370.
- ⟨ Convert a *brace_level* = 0 character 376 ⟩ Used in section 370.
- ⟨ Convert the accented or foreign character, if necessary 372 ⟩ Used in section 371.
- ⟨ Convert, then remove the control sequence 374 ⟩ Used in section 372.
- ⟨ Copy name and count *commas* to determine syntax 387 ⟩ Used in section 382.
- ⟨ Copy the macro string to *field_vl_str* 260 ⟩ Used in section 259.
- ⟨ Count the text characters 442 ⟩ Used in section 441.
- ⟨ Declarations for executing *builtin* functions 343 ⟩ Used in section 325.
- ⟨ Define the option table 468*, 471*, 474*, 475*, 476* ⟩ Used in section 467*.
- ⟨ Define *parse_arguments* 467* ⟩ Used in section 10*.
- ⟨ Determine the case-conversion type 366 ⟩ Used in section 364.
- ⟨ Determine the number of names 427 ⟩ Used in section 426.
- ⟨ Determine the width of this accented or foreign character 453 ⟩ Used in section 452.
- ⟨ Determine the width of this special character 452 ⟩ Used in section 451.
- ⟨ Determine where the first name ends and von name starts and ends 396 ⟩ Used in section 395.

- ⟨ Do a full brace-balanced scan 256 ⟩ Used in section 253.
- ⟨ Do a full scan with *bib_brace_level* > 0 257 ⟩ Used in section 256.
- ⟨ Do a quick brace-balanced scan 254 ⟩ Used in section 253.
- ⟨ Do a quick scan with *bib_brace_level* > 0 255 ⟩ Used in section 254.
- ⟨ Do a straight insertion sort 304 ⟩ Used in section 303.
- ⟨ Do the partitioning and the recursive calls 306 ⟩ Used in section 303.
- ⟨ Draw out the median-of-three partition element 305 ⟩ Used in section 303.
- ⟨ Execute a field 327* ⟩ Used in section 325.
- ⟨ Execute a *built_in* function 341 ⟩ Used in section 325.
- ⟨ Execute a *str_entry_var* 329* ⟩ Used in section 325.
- ⟨ Execute a *str_global_var* 330* ⟩ Used in section 325.
- ⟨ Execute a *wiz_defined* function 326 ⟩ Used in section 325.
- ⟨ Execute an *int_entry_var* 328 ⟩ Used in section 325.
- ⟨ Figure out how to output the name tokens, and do it 412 ⟩ Used in section 411.
- ⟨ Figure out the formatted name 402 ⟩ Used in section 420.
- ⟨ Figure out what this letter means 405 ⟩ Used in section 403.
- ⟨ Figure out what tokens we'll output for the 'first' name 407 ⟩ Used in section 405.
- ⟨ Figure out what tokens we'll output for the 'jr' name 410 ⟩ Used in section 405.
- ⟨ Figure out what tokens we'll output for the 'last' name 409 ⟩ Used in section 405.
- ⟨ Figure out what tokens we'll output for the 'von' name 408 ⟩ Used in section 405.
- ⟨ Final initialization for *.bib* processing 224 ⟩ Used in section 223*.
- ⟨ Final initialization for processing the entries 276 ⟩ Used in section 223*.
- ⟨ Finally format this part of the name 411 ⟩ Used in section 403.
- ⟨ Finally output a full token 414 ⟩ Used in section 413.
- ⟨ Finally output a special character and exit loop 416 ⟩ Used in section 415.
- ⟨ Finally output an abbreviated token 415 ⟩ Used in section 413.
- ⟨ Finally output the inter-token string 417 ⟩ Used in section 413.
- ⟨ Finally output the name tokens 413 ⟩ Used in section 412.
- ⟨ Find the lower-case equivalent of the *cite_info* key 270 ⟩ Used in section 268.
- ⟨ Find the parts of the name 395 ⟩ Used in section 382.
- ⟨ Form the appropriate prefix 444* ⟩ Used in section 443.
- ⟨ Form the appropriate substring 438* ⟩ Used in section 437.
- ⟨ Format this part of the name 403 ⟩ Used in section 402.
- ⟨ Get the next field name 275 ⟩ Used in section 274.
- ⟨ Get the next function of the definition 189 ⟩ Used in section 187*.
- ⟨ Globals in the outer block 2*, 16*, 19, 24, 30, 34, 37*, 41*, 43, 48*, 65*, 74, 76, 78, 80, 89, 91, 97*, 104, 117*, 124, 129*, 147, 161*, 163, 195, 219*, 247, 290*, 331, 337*, 344*, 365, 469*, 472* ⟩ Used in section 10*.
- ⟨ Handle a discretionary *tie* 419 ⟩ Used in section 411.
- ⟨ Handle this *.aux* name 103 ⟩ Used in section 100*.
- ⟨ Handle this accented or foreign character (and **return**) 399 ⟩ Used in section 398.
- ⟨ Initialize the option variables 470*, 473* ⟩ Used in section 467*.
- ⟨ Initialize the *field_info* 225 ⟩ Used in section 224.
- ⟨ Initialize the *int_entry_vars* 287* ⟩ Used in section 276.
- ⟨ Initialize the *sorted_cites* 289 ⟩ Used in section 276.
- ⟨ Initialize the *str_entry_vars* 288* ⟩ Used in section 276.
- ⟨ Initialize things for the *cite_list* 227 ⟩ Used in section 224.
- ⟨ Insert a *field* into the hash table 172 ⟩ Used in section 171.
- ⟨ Insert a *str_entry_var* into the hash table 176 ⟩ Used in section 175.
- ⟨ Insert a *str_global_var* into the hash table 216* ⟩ Used in section 215.
- ⟨ Insert an *int_entry_var* into the hash table 174 ⟩ Used in section 173.
- ⟨ Insert an *int_global_var* into the hash table 202 ⟩ Used in section 201.
- ⟨ Insert pair into hash table and make *p* point to it 71* ⟩ Used in section 68*.

- ⟨ Isolate the desired name 383 ⟩ Used in section 382.
- ⟨ Labels in the outer block 109, 146 ⟩ Used in section 10*.
- ⟨ Local variables for initialization 23*, 66 ⟩ Used in section 13*.
- ⟨ Make sure this entry is ok before proceeding 273 ⟩ Used in section 267.
- ⟨ Make sure this entry's database key is on *cite_list* 269 ⟩ Used in section 268.
- ⟨ Name-process a *comma* 389 ⟩ Used in section 387.
- ⟨ Name-process a *left_brace* 390 ⟩ Used in section 387.
- ⟨ Name-process a *right_brace* 391 ⟩ Used in section 387.
- ⟨ Name-process a *sep_char* 393 ⟩ Used in section 387.
- ⟨ Name-process a *white_space* 392 ⟩ Used in section 387.
- ⟨ Name-process some other character 394 ⟩ Used in section 387.
- ⟨ Open a *.bib* file 123* ⟩ Used in section 120.
- ⟨ Open the *.bst* file 127* ⟩ Used in section 126.
- ⟨ Open this *.aux* file 141* ⟩ Used in section 140.
- ⟨ Perform a **reverse** command 298 ⟩ Used in section 212.
- ⟨ Perform a **sort** command 299 ⟩ Used in section 214.
- ⟨ Perform an **execute** command 296 ⟩ Used in section 178.
- ⟨ Perform an **iterate** command 297 ⟩ Used in section 203.
- ⟨ Perform the case conversion 370 ⟩ Used in section 364.
- ⟨ Perform the purification 431 ⟩ Used in section 430.
- ⟨ Pre-define certain strings 75, 79, 334*, 339, 340 ⟩ Used in section 336.
- ⟨ Print all *.bib*- and *.bst*-file information 457 ⟩ Used in section 456.
- ⟨ Print all *cite_list* and entry information 458 ⟩ Used in section 456.
- ⟨ Print entry information 459* ⟩ Used in section 458.
- ⟨ Print entry integers 461 ⟩ Used in section 459*.
- ⟨ Print entry strings 460* ⟩ Used in section 459*.
- ⟨ Print fields 462* ⟩ Used in section 459*.
- ⟨ Print the job *history* 466 ⟩ Used in section 455.
- ⟨ Print the string pool 464 ⟩ Used in section 456.
- ⟨ Print the *wiz_defined* functions 463 ⟩ Used in section 456.
- ⟨ Print usage statistics 465 ⟩ Used in section 456.
- ⟨ Procedures and functions for about everything 12, 477*, 478* ⟩ Used in section 10*.

- ⟨ Process a *.bib* command 239 ⟩ Used in section 238.
- ⟨ Process a **comment** command 241 ⟩ Used in section 239.
- ⟨ Process a **preamble** command 242* ⟩ Used in section 239.
- ⟨ Process a **string** command 243 ⟩ Used in section 239.
- ⟨ Process a possible command line 102* ⟩ Used in section 10*.

- ⟨ Process the appropriate `.bst` command 155 ⟩ Used in section 154.
- ⟨ Process the string if we've already encountered it 70* ⟩ Used in section 68*.
- ⟨ Purify a special character 432 ⟩ Used in section 431.
- ⟨ Purify this accented or foreign character 433 ⟩ Used in section 432.
- ⟨ Push 0 if the string has a non*white_space* char, else 1 381 ⟩ Used in section 380.
- ⟨ Push the `.aux` stack 140 ⟩ Used in section 139.
- ⟨ Put this cite key in its place 272 ⟩ Used in section 267.
- ⟨ Put this name into the hash table 107 ⟩ Used in section 103.
- ⟨ Read and execute the `.bst` file 151* ⟩ Used in section 10*.
- ⟨ Read the `.aux` file 110* ⟩ Used in section 10*.
- ⟨ Read the `.bib` file(s) 223* ⟩ Used in section 211.
- ⟨ Remove leading and trailing junk, complaining if necessary 388* ⟩ Used in section 387.
- ⟨ Remove missing entries or those cross referenced too few times 283 ⟩ Used in section 276.
- ⟨ Scan a macro name 259 ⟩ Used in section 250.
- ⟨ Scan a number 258 ⟩ Used in section 250.
- ⟨ Scan a quoted function 192 ⟩ Used in section 189.
- ⟨ Scan a *str_literal* 191 ⟩ Used in section 189.
- ⟨ Scan an already-defined function 199 ⟩ Used in section 189.
- ⟨ Scan an *int_literal* 190 ⟩ Used in section 189.
- ⟨ Scan for and process a `.bib` command or database entry 236 ⟩ Used in section 210.
- ⟨ Scan for and process a `.bst` command 154 ⟩ Used in section 217.
- ⟨ Scan for and process an `.aux` command 116 ⟩ Used in section 143.
- ⟨ Scan the appropriate number of characters 445 ⟩ Used in section 444*.
- ⟨ Scan the entry type or scan and process the `.bib` command 238 ⟩ Used in section 236.
- ⟨ Scan the entry's database key 266 ⟩ Used in section 236.
- ⟨ Scan the entry's list of fields 274 ⟩ Used in section 236.
- ⟨ Scan the list of *fields* 171 ⟩ Used in section 170.
- ⟨ Scan the list of *int_entry_vars* 173 ⟩ Used in section 170.
- ⟨ Scan the list of *str_entry_vars* 175 ⟩ Used in section 170.
- ⟨ Scan the macro definition-string 209 ⟩ Used in section 208.
- ⟨ Scan the macro name 206 ⟩ Used in section 205.
- ⟨ Scan the macro's definition 208 ⟩ Used in section 205.
- ⟨ Scan the string's definition field 246 ⟩ Used in section 243.
- ⟨ Scan the string's name 244 ⟩ Used in section 243.
- ⟨ Scan the *wiz_defined* function name 181 ⟩ Used in section 180.
- ⟨ See if we have an "and" 386 ⟩ Used in section 384.
- ⟨ Set initial values of key variables 20, 25, 27*, 28*, 32*, 33*, 35, 67, 72, 119, 125, 131, 162, 164, 196, 292 ⟩ Used in section 13*.
- ⟨ Skip over *ex_buf* stuff at *brace_level* > 0 385 ⟩ Used in section 384.
- ⟨ Skip over *name_buf* stuff at *nm_brace_level* > 0 400 ⟩ Used in section 397.
- ⟨ Skip to the next database entry or `.bib` command 237 ⟩ Used in section 236.
- ⟨ Slide this cite key down to its permanent spot 285* ⟩ Used in section 283.
- ⟨ Start a new function definition 194 ⟩ Used in section 189.
- ⟨ Store the field value for a command 262 ⟩ Used in section 261.
- ⟨ Store the field value for a database entry 263* ⟩ Used in section 261.
- ⟨ Store the field value string 261 ⟩ Used in section 249.
- ⟨ Store the string's name 245 ⟩ Used in section 244.
- ⟨ Subtract cross-reference information 279* ⟩ Used in section 276.
- ⟨ Swap the two strings (they're at the end of *str_pool*) 440 ⟩ Used in section 439.
- ⟨ The procedure *initialize* 13* ⟩ Used in section 10*.
- ⟨ The scanning function *compress_bib_white* 252 ⟩ Used in section 248.
- ⟨ The scanning function *scan_a_field_token_and_eat_white* 250 ⟩ Used in section 248.

- ⟨ The scanning function *scan.balanced_braces* 253 ⟩ Used in section 248.
- ⟨ Types in the outer block 22*, 31, 36, 42*, 49*, 64*, 73*, 105, 118*, 130*, 160*, 291*, 332 ⟩ Used in section 10*.
- ⟨ *execute_fn* itself 325 ⟩ Used in section 342.
- ⟨ *execute_fn*(*) 350 ⟩ Used in section 342.
- ⟨ *execute_fn*(+) 348 ⟩ Used in section 342.
- ⟨ *execute_fn*(-) 349 ⟩ Used in section 342.
- ⟨ *execute_fn*(:=) 354 ⟩ Used in section 342.
- ⟨ *execute_fn*(<) 347 ⟩ Used in section 342.
- ⟨ *execute_fn*(=) 345 ⟩ Used in section 342.
- ⟨ *execute_fn*(>) 346 ⟩ Used in section 342.
- ⟨ *execute_fn*(add.period\$) 360 ⟩ Used in section 342.
- ⟨ *execute_fn*(call.type\$) 363 ⟩ Used in section 341.
